

## Lecture 8: Text classification

William Webber ([william@williamwebber.com](mailto:william@williamwebber.com))

COMP90042, 2014, Semester 1, Lecture 8

# What we'll learn in this lecture

- ▶ The classification process
- ▶ Two simple text classification methods tied closely to vector-space model:
  - ▶  $k$  nearest neighbours
  - ▶ Rocchio
- ▶ How to evaluate classification systems

# Classification vs. clustering

- ▶ Clustering: unsupervised; machine chooses classes
- ▶ Classification: supervised; we specify classes
- ▶ Clustering: docs clustered by self-similarity
- ▶ Classification: docs classified by similarity to examples

# Classification, regression, ranking

**Regression** estimate real output variable for doc

**Ranking** rank docs by some quality

**Classification** assign class to doc

- ▶ Binary (two-class) classification:
  - ▶ Regressed score can be probability, degree
  - ▶ If scores only relative,  $\rightarrow$  ranking
  - ▶ Bifurcation at score  $\rightarrow$  classification
- ▶ Many binary classification methods go score  $\rightarrow$  class
- ▶  $c$  multi-class from  $c$  binary regressions

# Classification: outline

## Types of classification

**Rule-based** Human writes rules, machine applies

**Decision tree** Machine learns (discrete) rules

**Statistical** Machine learns statistical models

## Statistical ML for classification

- ▶ Human labels example objects with classes (training data)
- ▶ Machine learns statistical model from examples
- ▶ Machine predicts class of unlabelled objects from model

## $k$ nearest-neighbours

- ▶ Predicted class of object  $d$
- ▶ ... plurality class of  $k$  training objects “nearest”  $d$
- ▶ Cosine distance a possible “nearness” metric for docs

## $k$ nearest-neighbours

9 6 6 5 4 0 7 4 0 1  
3 1 3 4 7 2 7 1 2 1  
1 7 4 2 3 5 1 2 4 4

### Pros

- ▶ Good effectiveness for text
- ▶ Handles multi-class directly
- ▶ Doesn't require model to be built
- ▶ Handles any concept of "similar"

# $k$ nearest-neighbours

## Cons

- ▶ Need to tune selection of  $k$  ( $\approx 40$  for text)
- ▶ Need to adjust for unbalanced classes
- ▶ **Computationally intensive** at classification time
  - ▶  $O(n)$  for naive method (compare each item)
  - ▶  $O(\log n)$  for divide-and-conquer methods

# Rocchio's method: intuition

- ▶ Saw Rocchio used for PRF (can you summarize?)
- ▶ Can also be used for classification
- ▶ Idea is:
  - ▶ Calculate mean from training docs in each class
  - ▶ Mean class document represents class
  - ▶ Classify new document by nearest class mean

## Rocchio's method: implementation

- ▶ Let  $\mathcal{T}_c$  be set of  $n$  training docs for class  $c$
- ▶ Centroid docvec  $\boldsymbol{\mu}_c$  of  $c$  is:

$$\boldsymbol{\mu}_c = \frac{1}{n} \sum_{d \in \mathcal{T}_c} \mathbf{v}(d) \quad (1)$$

where  $\mathbf{v}(d)$  is the docvec of  $d$

- ▶ Then assigned class  $c \in \mathcal{C}$  for unlabelled doc  $d$  is:

$$c = \operatorname{argmax}_{c' \in \mathcal{C}} \cos(\boldsymbol{\mu}_{c'}, \mathbf{v}(d)) \quad (2)$$

# Rocchio's method: the model

- ▶ Generally less effective than  $k$ NN
- ▶ (though more effective on text data than Naive Bayes)
- ▶ Much faster to compute at run time

## The model

- ▶ In Rocchio,  $\mu_c$  is *model* of class  $c$ .
- ▶ Document  $d$  tested for (strength of) membership in class  $c$  using dot product
- ▶ Constant time (relative to collection size)

## Classification: outline (bis)

- ▶ Human labels example objects with classes (training data)
- ▶ Machine learns statistical model from examples
- ▶ Machine predicts class of unlabelled objects from model

## Classifier: labelling

- ▶ User identifies classes  $\mathcal{C} = \{c_1, c_2, \dots, c_n\}$
- ▶ User finds, or system samples, training documents  $\mathcal{T}$
- ▶ User labels each document  $d \in \mathcal{T}$  with its class
- ▶ Output is set  $\mathcal{T}_c$  of training examples for each class  $c$

# Classifier: features

Require calculable representation of objects to be classified

- ▶ Identify set of discrete *features*
- ▶ Each object represented as a *feature vector*
  - ▶ each cell represents a feature
  - ▶ value of cell is object's weight for that feature
- ▶ Result is an object  $\times$  feature matrix

# Learning algorithm

- ▶ Machine learner learns *model*
  - ▶ Of class  $c$  from training examples  $\mathcal{T}_c$
  - ▶ Or of overall classification decision (esp. multi-class)
- ▶ A model is a function that:
  - ▶ Takes a feature vector as input
  - ▶ Produces either:
    - ▶ Strength of membership to each class  $c \in \mathcal{C}$ , or
    - ▶ Single class assignment  $c$ , as output
- ▶ Models can work by:
  - ▶ Similarity ( $k$ NN, Rocchio)
  - ▶ Formula (esp. for regression; e.g. linear least squares)
  - ▶ Discrimination (finding “dividing line”, e.g. SVM)

# Features in text classification

For text classification:

- ▶ Objects are documents
- ▶ Terms are features
- ▶ Weights are (e.g. TF\*IDF) weights

Text, compared to other forms of classification:

- ▶ Very large feature set (“for free”)
  - ▶ Feature design big issue elsewhere (e.g. image recognition)
- ▶ Highly correlated
  - ▶ NB works poorly without feature selection
- ▶ Sparse (most features have 0 weight for most objects)

# Enhancing the feature space

- ▶ Can add non-text document aspects as features:
  - ▶ Author, length, date (with caution) of document
  - ▶ Sender, recipient of email
  - ▶ Noun phrases or  $n$ -grams
  - ▶ Number of punctuation marks, etc. etc.
- ▶ Enhancing features a “value add” for specialist applications

(Rough) decreasing order of importance for good classifier:

1. More training data
2. Better features
3. Better classification algorithm

# Evaluation of (text) classification

- ▶ Classifier tested against labelled datasets
  - ▶ Dataset should be fully labelled
  - ▶ Often re-use set created by real-world process
- ▶ Classifier trained against one set of docs
- ▶ Then asked to predict labels of another set
  - ▶ Training and test set must be kept separate!
- ▶ Effectiveness measured by accuracy of prediction

Two cases:

1. Output is class assignment (set-based evaluation)
2. Output is strength of class membership (esp. for binary classification)

## Set-based Evaluation metrics

Label	True		
	1	0	
Predicted	1	TP	FP
	0	FN	TN

$$\frac{TP + TN}{TP + FP + FN + TN}$$

Accuracy

$$\frac{2 \cdot TP}{2 \cdot TP + FP + FN}$$

F1 score

$$\frac{TP}{TP + FN}$$

Sensitivity (TPR, Recall)

$$\frac{TN}{FP + FN}$$

Specificity (TNR)

# Set-based evaluation metrics

- ▶ Accuracy is sensitive to imbalanced classes
  - ▶ If 95% objects in class  $c$ , always guessing class  $c$  gets 95% accuracy
- ▶ F1 score (harmonic mean of recall and precision)
  - ▶ Also an IR metric
  - ▶ More robust to imbalance
  - ▶ Doesn't generalize (easily) to multiple classes
- ▶ Sensitivity and specificity generally used as ingredients in rank metrics (see next)

# Rank metrics

- ▶ Binary classification often a “A” vs. “not-A” task
  - ▶ E.g. “about sports” vs. “not about sports”
  - ▶ I.e. “relevant” vs. “not relevant” to sports
- ▶ Many classifiers give real-valued prediction
- ▶ Can rank by decreasing association to class  $A$ 
  - ▶ Cutoff point may be selected for binarization
- ▶ Ranking can be independently evaluated:
  - ▶ To evaluated quality of ranking (vs. of cutoff)
  - ▶ Because ranking might be end product

# Rank metrics

- ▶ General IR rank metrics (e.g. AP) can be used
- ▶ Common alternative to graph contrasting measures down ranking
  - ▶ e.g. TPR vs FPR (sensitivity vs.  $1 - \text{specificity}$ ) at increasing ranks
- ▶ Then calculate “area under curve” (AUC) to give single measure
  - ▶ Area under TPR vs. FPR known as receiver operating characteristic, or ROC curve, or (confusingly) area under the ROC curve, or AUROC, or even AUC

## RCV1-v2

CCAT	—————	Corporate/Industrial
C11	—————	Strategy/Plans
C15	—————	Performance
C151	—————	Accounts / Earnings
C1511	—	Annual Results
C152	—————	Comment / Forecasts

Figure : Some RCV1v2 categories

- ▶ LYRL-30k drawn from RCV1-v2
- ▶ 800k-odd Reuters news articles
- ▶ 103 topical labels, manually assigned by Reuters curators
- ▶ Topics arranged in hierarchy
- ▶ One document can be labelled with more than one topic

# Looking back and forward

## Back

- ▶ Classification process: train, learn, predict
- ▶  $k$ NN and Rocchio, simple VSM classifiers
- ▶ ... follow directly from VSM search, clustering approaches
- ▶ Set-based and ranking-based classifier evaluation

# Looking back and forward

## Forward

- ▶ Next lecture: support vector machines (SVM)
  - ▶ Robust and popular classifier family
  - ▶ Also based on a geometric model
- ▶ Later in course: probabilistic classification models

## Further reading

- ▶ Lewis, Yang, Rose, and Li, “RCV1: A New Benchmark Collection for Text Categorization Research” (JMLR, 2004) (describes the RCV1v2 collection; also gives comparative scores for  $k$ NN, Rocchio, and SVM)
- ▶ Yang and Liu, “A re-examination of text categorization methods” (SIGIR, 1999) (compares  $k$ NN, Naive Bayes, and SVM)
